Feld-Emissionen einer jungen *Sphagnum* Kultur

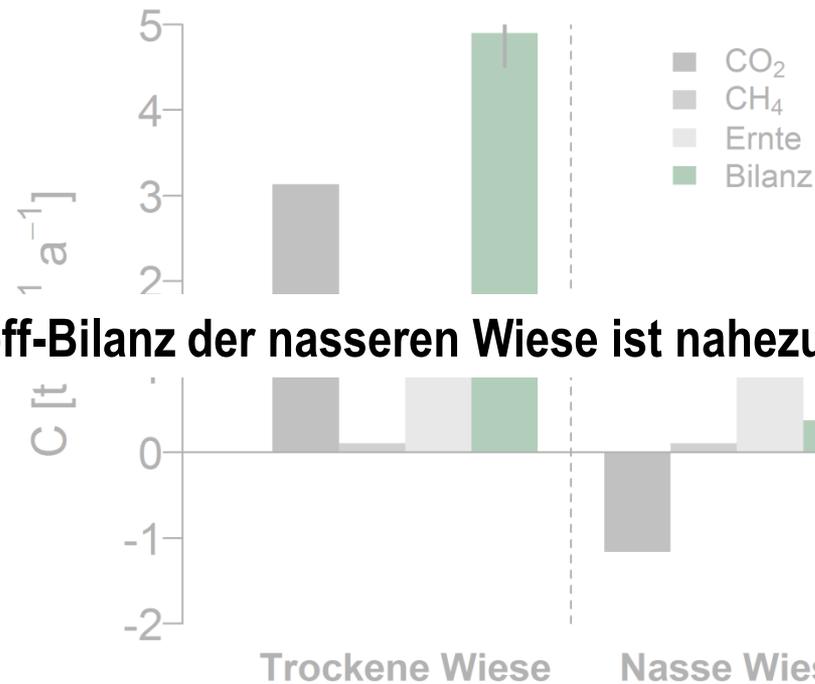

Sphagnum farming Gebiete sind THG-Senken während der Etablierungsphase

Ist die Nutzung torfschonend?

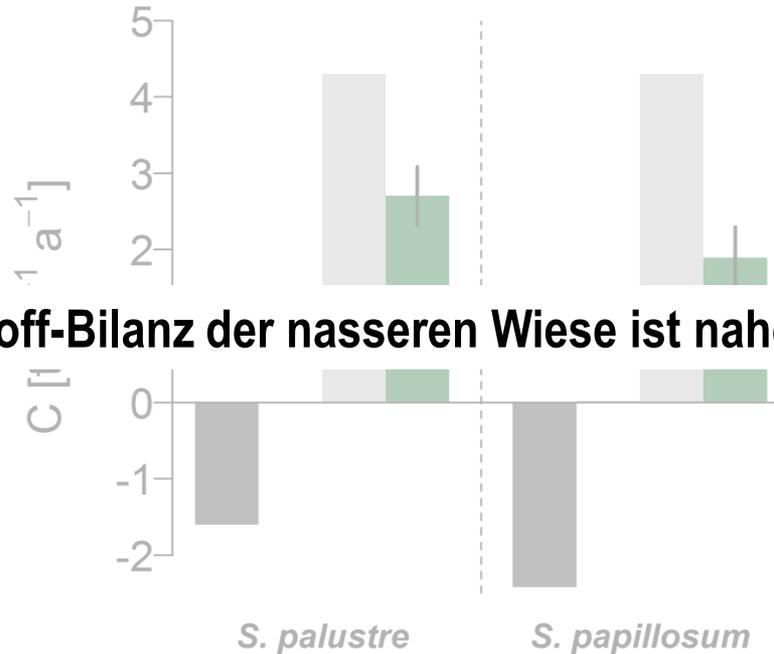

Ist die Nutzung torfschonend?

Die Kohlenstoff-Bilanz der nasseren Wiese ist nahezu ausgeglichen

Ist die Nutzung torfschonend?

Die Kohlenstoff-Bilanz der nasseren Wiese ist nahezu ausgeglichen

Zusammenfassung

Paludikultur hatte keine negativen Auswirkungen auf die Feld-Emissionen der untersuchten Systeme.

Die hohen Wasserstände scheinen große Kohlenstoff-Verluste effektiv zu verhindern.

Nächste Schritte:

- Analyse eines gesamten Produktionszyklus von *Sphagnum* farming und Erlenanbau
- Längerfristige und größermaßstäbige Feld-Experimente der Schilf-Paludikultur

→ Bewertung der Klimarelevanz von Paludikultur-Produkten (Life-cycle Analyse)

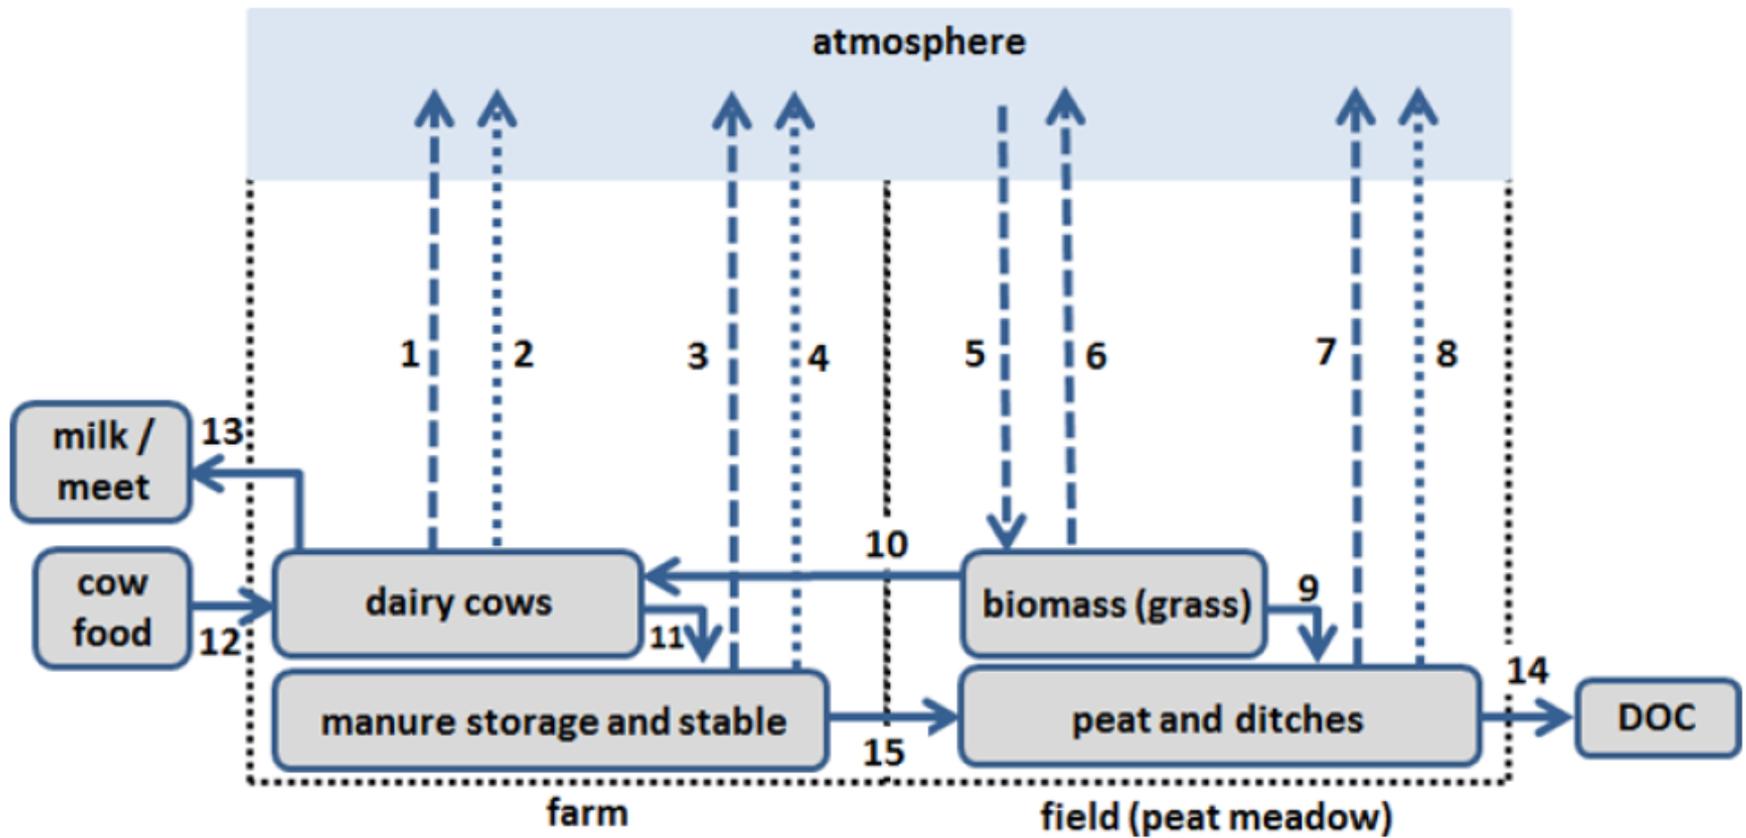

Thank you!

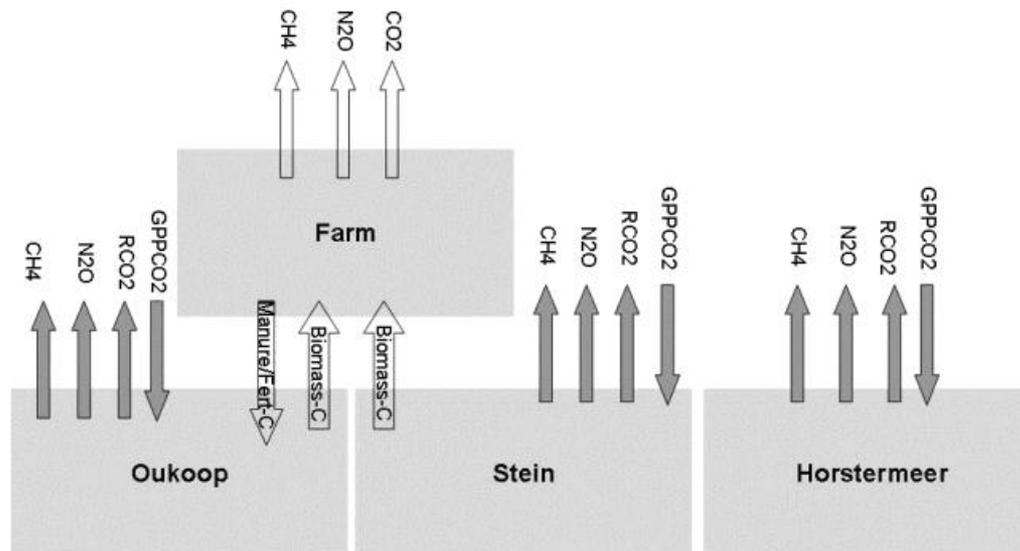

Figure 1. Ecosystem and farm-based GHG fluxes (CO_2 respiration (RCO_2), CO_2 gross primary production or photosynthesis (GPPCO_2), CH_4 and N_2O) and carbon fluxes ($\text{CO}_2\text{-C}$), $\text{CH}_4\text{-C}$, manure and fertilizer C, biomass C that are being considered in the current study for Oukoop, Stein and Horstermeer. White arrows are farm-related fluxes and dark-grey arrows are ecosystem fluxes.

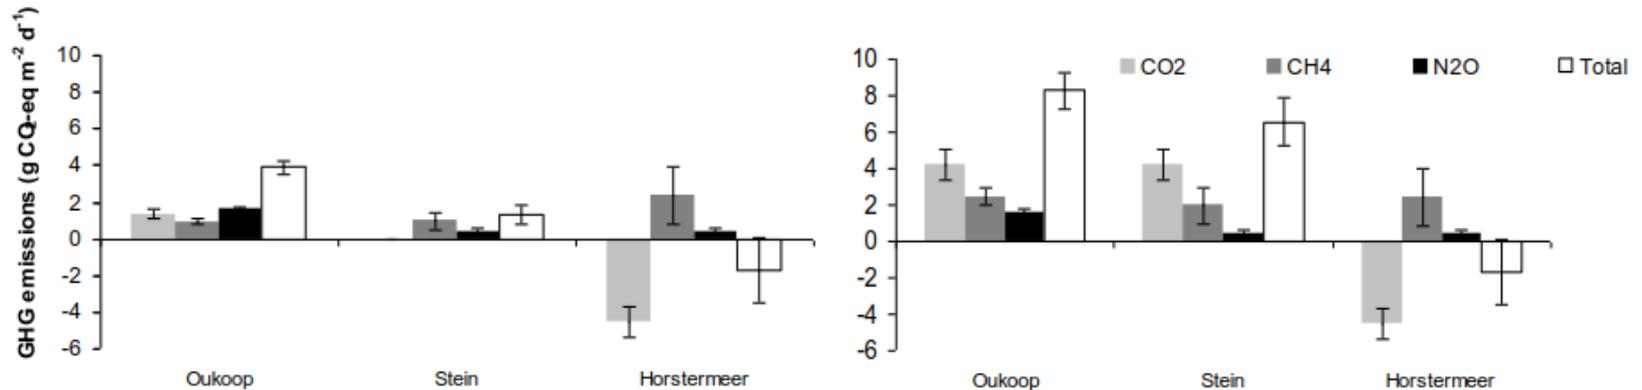

Figure 8. The GHG balances including CO₂, CH₄ and N₂O for the three sites: intensive (Oukoop), extensive (Stein) and restored (Horstermeer). The figure on the left represents ecosystem emissions, excluding farm-based CH₄ and CO₂ emissions, and on the right including farm-based CH₄ and CO₂ emissions, averaged over 2006, 2007 and 2008 (fluxes are given in warming potentials, g CO₂-eq m⁻² d⁻¹). All fluxes are given in g CO₂-eq m⁻² d⁻¹. The error bars for CO₂, CH₄ and N₂O represent the standard deviation of the mean for 3 years of measurements based on daily values.

Was passiert mit der geernteten Biomasse?

ecosystem carbon balance (NECB), which was calculated by using equation 13 (Chapin et al. 2006). DOC was estimated to 26 kg C ha⁻¹a⁻¹ according to Moore (1987). Values of DIC, CO and VOC are assumed to be negligible and not considered.

$$\text{NECB} = -\text{NEE} + F_{\text{CO}} + F_{\text{CH}_4} + F_{\text{VOC}} + F_{\text{DOC}} + F_{\text{DIC}} + F_{\text{PC}}$$

equation 13

$$\text{NECB} = dC dt^{-1}$$

NEE = net ecosystem exchange (g CO₂-C m⁻² a⁻¹)

F_{CO} = net carbon monoxide absorption [or -efflux (negative sign)](g CO-C m⁻² a⁻¹)

F_{CH₄} = net methane consumption [or -efflux (negative sign)] (g CH₄-C m⁻² a⁻¹)

F_{VOC} = net volatile organic C absorption [or -efflux (negative sign)] (g VOC-C m⁻² a⁻¹)

F_{DOC} = net dissolved org. C input to the ecosystem [or net DOC leaching loss (neg. sign)] (g DOC-C m⁻² a⁻¹)

F_{DIC} = net dissolved inorganic C input [or net DIC leaching loss (neg. sign)] (g DIC-C m⁻² a⁻¹)

F_{PC} = net lateral transfer of particulate (nondissolved, nongaseous) C into the ecosystem [or out of (negative sign)], e.g. harvest (g PC-C m⁻² a⁻¹)

A widely-used technique to establish the climatic relevance of the greenhouse gas exchange at each site, expressed as CO₂-equivalents, is the global warming potential (GWP) methodology (equation 14) (Drösler 2005, IPCC 2007, Beetz et al. 2013). In general, the global warming

References

F_{VOC}	= net volatile organic C absorption [or -efflux (negative sign)] (g VOC-C m ⁻² a ⁻¹)
F_{DOC}	= net dissolved org. C input to the ecosystem [or net DOC leaching loss (neg. sign)] (g DOC-C m ⁻² a ⁻¹)
F_{DIC}	= net dissolved inorganic C input [or net DIC leaching loss (neg. sign)] (g DIC-C m ⁻² a ⁻¹)
F_{PC}	= net lateral transfer of particulate (nondissolved, nongaseous) C into the ecosystem [or out of (negative sign)], e.g. harvest (g PC-C m ⁻² a ⁻¹)

A widely-used technique to establish the climatic relevance of the greenhouse gas exchange at each site, expressed as CO₂-equivalents, is the global warming potential (GWP) methodology (equation 14) (Drösler 2005, IPCC 2007, Beetz et al. 2013). In general, the global warming potential over a time span of 100 years is taken (Drösler 2005). Positive values represent efflux of CO₂-equivalents into the atmosphere.

GWP balance [g CO₂-eq. m⁻²] = NEE · GWP_{CO₂} + F_{CH₄} · GWP_{CH₄} + F_{N₂O} · GWP_{N₂O} equation 14

GWP_{CO₂} = 1

GWP_{CH₄} = 72 (20 years), 25 (100 years), 7.6 (500 years)

GWP_{N₂O} = 289 (20 years), 298 (100 years), 153 (500 years)

2.2.6 Statistical analyses

Average values are arithmetic means +/- standard error.

Error analysis of CO₂ gas fluxes was conducted by calculating the standard error for each
